

Algorithm:

Step 1: Input & Initialization

- a. Read number of vertices V
 - b. Read adjacency matrix $\text{graph}[V][V]$
 - c. Create:
 $\text{path}[V] \rightarrow$ stores cycle
 $\text{visited}[V] \rightarrow$ marks visited vertices
-

Step 2: Start Setup (findCycle)

- a. Initialize:
 $\text{path}[i] = -1$ for all i
 $\text{visited}[i] = \text{false}$ for all i
 - b. Start from vertex 0:
 $\text{path}[0] = 0$
 $\text{visited}[0] = \text{true}$
 - c. Call $\text{solve}(1)$
-

Step 3: Recursive Function: $\text{solve}(\text{pos})$

- a. Base Case
if $\text{pos} == V$:
if $\text{graph}[\text{path}[V-1]][\text{path}[0]] == 1$:
return true
else:
return false
 - b. Try all vertices
for $v = 1$ to $V-1$:
-

Step 4: Safety Check ($\text{isSafe}(v, \text{pos})$)

- a. Vertex v is valid if:
 $\text{graph}[\text{path}[\text{pos}-1]][v] == 1$
 $\text{visited}[v] == \text{false}$
-

Step 5: Place Vertex

- a. `path[pos] = v`
 - b. `visited[v] = true`
-

Step 6: Recurse

- a. `if solve(pos + 1) == true:`
`return true`
-

Step 7: Backtrack

- a. `visited[v] = false`
 - b. `path[pos] = -1`
-

Step 8: If All Fail

- `return false`
-

Step 9: Final Output

- a. If solution found $\rightarrow$ print cycle
- b. Else $\rightarrow$ print "No Hamiltonian Cycle exists"
